

1. The first group of variables includes the demographic characteristics of the respondents, such as age, gender, and education level. These variables are used to control for potential confounding factors that may influence the relationship between the independent and dependent variables.

2. The second group of variables represents the independent variables, which are the factors being manipulated or observed in the study. These variables are hypothesized to have a direct effect on the dependent variable.

3. The third group of variables consists of the dependent variable, which is the outcome or response being measured in the study. This variable is the primary focus of the research and is expected to be influenced by the independent variables.

4. The fourth group of variables includes control variables, which are used to account for other factors that may affect the relationship between the independent and dependent variables. These variables are typically measured at the same time as the independent variables to ensure that the results are not biased by external factors.

5. The fifth group of variables represents the interaction terms, which are used to test for potential moderating effects. These terms are created by multiplying the independent variables together to see if the relationship between them changes depending on the values of the other variables.

6. The sixth group of variables includes the error term, which represents the unexplained variance in the dependent variable. This term is used to account for any random noise or measurement error that may be present in the data.

7. The seventh group of variables consists of the regression coefficients, which are the parameters estimated by the regression model. These coefficients represent the strength and direction of the relationship between the independent variables and the dependent variable.

8. The eighth group of variables includes the adjusted R-squared value, which is a measure of the model's goodness of fit. This value indicates the proportion of the variance in the dependent variable that is explained by the independent variables, adjusted for the number of predictors in the model.

9. The ninth group of variables represents the F-statistic, which is used to test the overall significance of the regression model. This statistic compares the model's performance to a null model and helps to determine if the independent variables have a significant effect on the dependent variable.

10. The tenth group of variables includes the p-values for each regression coefficient, which are used to test the significance of individual predictors. These values indicate the probability of observing the estimated coefficient if the true coefficient is zero, and they help to identify which independent variables have a statistically significant effect on the dependent variable.
